<b>JOB MARKET PAPER</b>	<b>Selection in Crisis Lending: Evidence from Chile's Government-Guaranteed Loan</b> with Cristián Sánchez	We study the long-run effectiveness of government-guaranteed loan programs implemented during recent crises. Using administrative and loan application data from the Central Bank of Chile, we track firm defaults five years after the COVID-19 shock. Our instrumental-variable estimates show that these loans postponed defaults for two years but did not reduce total defaults over the long run. Banks used private information to direct credit toward firms that would have been safer even without the program. To assess the welfare implications of the delays in defaults and banks' selection of safer firms, we build a dynamic model of heterogeneous entrepreneurs disciplined by our causal estimates. The program generated welfare gains exceeding its fiscal cost by 21%, with limited rents for banks and modest increases in aggregate risk-taking. Younger, high-growth firms are the most cost-effective group to support, yet they are the least likely to be approved since they have larger default risk. A budget-neutral redesign that raises guarantees for younger firms and reduces them for the rest could increase welfare by 6pp, suggesting that firm age is a practical basis for targeting future crisis lending policies.
<b>WORKING PAPERS</b>	<b>Asset Returns as Carbon Taxes</b> with Monika Piazzesi, Martin Schneider and Marcelo Sena	In frictionless financial markets, a carbon tax on energy users provides the same incentives as a <i>replicating return schedule</i> that depends on firms' emission intensities, defined as scope 1 emissions relative to enterprise value. We use this result to interpret pollution premia measured by recent empirical studies and conclude that markets currently provide only modest incentives. Replicating a serious carbon tax requires high returns in the right tail of the emission intensity distribution. With heterogeneous investors, such returns are not sustainable unless essentially everyone perceives large nonpecuniary costs from holding dirty capital. Substantial emission reductions can be achieved, however, when even a small share of investors perceive nonpecuniary <i>benefits</i> from owning clean electricity capital.
	<b>Pricing and Financial Incentives in Sovereign Green Debt: Evidence from Chile</b> with Marcelo Sena	We study the pricing of sovereign green bonds using Chile's pioneering green bond program and its cross-design issuance. Employing a panel of Chilean U.S.-dollar bonds, we estimate no-arbitrage pricing kernels for green and conventional bonds. The results reveal a declining greenium across maturities, driven by the higher interest rate risk exposure of green bonds. We find no evidence of investor segmentation or liquidity differences between green and conventional bonds. Instead, we explain the observed pricing patterns through a representative-agent asset-pricing model in which investors derive nonpecuniary benefits from the real value of their green bond holdings. During high-inflation periods, as observed in our sample, the real value of green bond portfolios deteriorates, making the convenience service they provide scarcer and more valuable. This positive correlation between green convenience yield and inflation generates a risk premium that compresses the greenium especially at longer maturities, producing a downward-sloping greenium term structure.

WORK IN PROGRESS	<b>The Cost of Port Disruptions: Evidence from U.S. Containerized Trade</b> with Stephen Redding, Janet Stefanov, and Shoshana Vasserman  How costly are disruptions to activity at U.S. ports? To answer this question, we estimate a model of demand for importers of different types of products who choose which maritime port (if any) to use for their container imports. Our estimator leverages a nearly comprehensive panel of maritime imports to the U.S. between 2020 and 2025, linking customs records, granular GPS pings from container-shipping fleets, origin-destination-level shipping prices, and a number of additional data sources. Using variation in prices and processing times from localized slowdowns and disruptions at different ports, our model rationalizes importers' port choices as a function of daily origin-destination prices, travel time at sea and on land, port congestion, and sticky product-origin-destination preferences at the time of each shipment's observed departure. Our estimates allow us to predict the economic incidence of a short-term disruption at a subset of ports, such as a general strike. We use this to discuss the potential of different policies to support supply chain resilience.	
ACADEMIC PUBLICATIONS	<b>From Bad to Worse: the Economic Impact of COVID-19 in Developing Countries. Evidence from Venezuela</b> with Germán Caruso, María Emilia Cucagna, Luis Pedro España <i>Latin American Economic Review, 2021</i>  Policy responses to COVID-19 affected the dynamic of economic growth and labor markets worldwide, hitting economically harder on developing countries. These policies involved economic lockdowns that included the shutdown of the main statistical exercises, making it almost impossible to assess the breadth and variety of their effects. Using a phone survey, this paper examines the impact of the quarantine implemented in Venezuela on labor market outcomes. The identification strategy exploits the exogenous variation in the severity of the lockdown in different regions of the country. The main result indicates a 16.5 percentage points reduction in employment, while in regions with severe lockdowns the reduction has been 13.8 p.p. larger. In particular, the self-employed and informally employed were hard hit by the lockdown. To cope with this effect, households sold their productive assets, reduced their savings, sought for alternative income sources and looked for help from relatives. This paper does not find a differential effect on the number of COVID-19 cases in more severe lockdown settings. Results are robust to endogenous migration and alternative specifications.
